DELIVERY REVIEW & SCOPE ANALYSIS

Salesman Portal

What was asked for, what has been delivered, and what Coach Aril's design adds on top of it.

Revised 19 October 2026 Prepared as a reference for discussion with Coach Aril

This revises the report of 8 October, and supersedes the revision of 15 October. Since the original a phone application has been built to Coach Aril's design and is running on the live database. **Eight of the nineteen additions identified below are now built**, and two more are partly built. The second week went into making the result trustworthy rather than larger: an audited acceptance run, a security and performance pass on the database, and a deeper reseller profile. Section 02a records what changed; every other section has been brought up to date against it.

10 Recommendation

11 Summary for the meeting

01

What this is based on

Two sources. The **MASTER FINAL requirement document** – sixteen modules, three transaction models, Customer Profile as the command center – which is the brief the current portal was built to. And roughly **forty screenshots** of Coach Aril's app design.

No working build of his version was available for testing, and two things were never shown: **Jadual Harian**, and **any management or admin side.** Where this report says something is absent from his design, that means *not seen* – not *proven absent*. Those appear as questions rather than findings.

Claims about the current build were checked directly against the live database.

VERIFIED	OBSERVED	INFERRED	UNKNOWN
Checked against the live database or the running portal	Clearly visible in Coach Aril's screenshots	A reasonable reading, not confirmed	Not determinable from what we have

---

02

What was delivered against the brief

MASTER FINAL specified sixteen modules and three transaction models. All sixteen are built, and running against a live database.

16 / 16	19	6	9
modules built	database tables, access-controlled	transaction functions, each all-or-nothing	business rules proven to refuse the wrong thing

	MODULE	DELIVERED
01	Register Customer / Outlet	Atomic registration, GPS capture, five photograph types, fifteen additional reseller fields added from his design
02	Senarai Outlet	Search on code, name, PIC, phone and WhatsApp
03	Jadual Harian	Day ordered by outstanding money, built to the brief's explicit exclusions
04	Order + Harga Tweak	Order posting with floor-price guard and live van deduction

	MODULE	DELIVERED
05	Delivery Order	Consignment only, with its own running number
06	Sales Order	Issued on sale, carries the DO it came from
07	Invoice	Issued from the SO, due date derived from payment term
08	Payment	Full and partial, updates outstanding and invoice status
09	Payment Receipt	Own running number, PDF and print
10	Product & Stock	Van stock per salesman, plus restocking with request, issue and reject
11	Return	RET document, stock returns to the van
12	Sales Ranking	Recalculates on every sale, five periods
13	PDF, WhatsApp, Print	All three, at 58mm and 80mm thermal widths
14	Running Number	Six sequences off a locked counter; 500 consecutive calls produced 500 distinct values
15	Payment & Stock Control	Enforced in the database, not in the screen
16	Refer & Earn	End to end, 5% on the first settled invoice

Four things were built that the brief never asked for, because the system would not have survived contact with real use without them:

- **Van restocking.** MASTER FINAL describes stock going out but never coming back. Without a restocking path, every van drains to zero and the system becomes unusable within a week of go-live.
- **A management panel.** Someone in the office has to see collections, ageing, stock and the team. It reads everything and posts nothing.
- **Four languages** – Bahasa Malaysia, English, Chinese and Iban, across 365 dictionary entries.
- **Account administration.** Opening a login, resetting a password and revoking access, without the master key ever reaching a phone.

02a

What changed since 8 October

On 8 October the answer to “can it look like Coach Aril's design?” was a shell that signed in and nothing more. Eleven days later it is a working phone application built to his screenshots, on the same live database, with an audited acceptance run behind it.

28	8 / 19	31	8 / 8
screens on the phone	of his additions now built	database migrations applied	acceptance criteria passing

The first week: the interface question

Everything below runs against real rows. Post an order on the phone and the van decrements, the invoice exists, the debt moves and the receipt prints — on another device, next week.

- **The salesman's day, end to end.** Registration in seven steps with GPS capture and five photographs; Ambil Order with three outcomes decided by payment term; the consignment balance check that bills only what sold; payment, receipt, returns; and Jadual Harian — a screen Coach Aril never supplied, built to the written requirement instead.
- **Every Cetak and Lihat button does something.** Delivery order, sales order, invoice, receipt and return, each on a 58mm or 80mm roll, with PDF, WhatsApp and print behind them. **Borang Konsainan** prints as a sheet of A4 with the terms and two signature blocks.
- **Four approval workflows, both halves.** The salesman raises; the office decides; and — this is the part his design does not show — the answer comes back to the salesman's phone, with the office's reason attached.
- **Documents can be cancelled.** Stock returns to the van, payments reverse, the consignment shelf gives the goods up, and the debt list, the day's takings and van stock all move together. The document stays on file, numbered, marked *Dibatalkan*.

The second week: making it trustworthy

Nothing in this week makes the application larger. It is the difference between a build that demonstrates well and one that can be put in front of money.

- **An audited acceptance run.** The eight criteria written into the project's own README, executed end to end as one cycle: an account created and revoked, stock issued, an outlet registered, a sale posted, a payment refused for exceeding

the balance, a return, and every management figure recomputed from the underlying rows. It runs through the application's own client with a real salesman's credentials — **no administrator key, no bypass** — because a validation that runs as an administrator proves nothing about what a salesman can reach. **43 checks, none failing.** The result is a dated note that also states plainly what it does *not* cover.

- **The database was locked down at the cause.** A linter found that every function in the schema was reachable over the API, including the internal ones that move van stock — the platform publishes new functions by default, so each one written had inherited it. The default is now deny, with access granted back only to the twenty-six the applications actually call, and that was verified from the outside by signing in as a salesman and trying each one. Fifteen are now unreachable.
- **And tuned.** Thirty row-level-security policies were re-evaluating the signed-in user for every row scanned; they now do it once per statement. Forty-three foreign keys gained a covering index.
- **The reseller profile became the screen it was meant to be.** Everything registration collects, shown only where it exists; how old the debt is and which invoices to chase first; when the shop last actually paid; the special prices the office has approved, checked against the current floor and list price; and what the outlet is still waiting on the office to answer.
- **The published build names the commit it came from.** It previously carried a hand-typed date that was three days stale. Without that, nobody can say what a tester tested.

STILL ONLY IN HIS DESIGN

Product flavours, multi-branch operation and free goods — the three that change the database. GPS route recording and the Kerja Harian log, both of which the requirement document explicitly excludes. Over Payment. The stock request as one numbered document. A full map tile.

IN NEITHER HIS DESIGN NOR THE BRIEF

Cancelling a document and reversing what it did. The salesman seeing what happened to his own requests. The office's record of its own decisions. These are not features anybody asked for — they are the things a system needs before real money moves through it.

THE PRACTICAL READING

The first week took the interface question off the table; the second answered whether the result can be trusted with real figures. What is left to decide is not *whose screens* – it is the three schema items, and the labels nobody outside his team can read. **Those are the only things genuinely blocking the next phase.**

Two things still stand between this and a real salesman's hands, and neither is an engineering problem: the company's **SSM number and registered address**, without which nothing the app prints is a valid commercial document, and a run on a **physical handset**, which no amount of automated testing replaces.

03

The two builds are different kinds of thing

COACH ARIL'S VERSION

A designed interface, broad and detailed, covering screens the current build presents differently. **The figures in it are hardcoded.** There is no database, no stored transaction, and nothing that survives closing the app.

It shows what the system should look like. It cannot yet record a sale.

THE CURRENT BUILD

A running system. Nineteen tables with access control enforced at the database, so a salesman querying another's outlets gets nothing back however he asks. Six transaction functions, each a single all-or-nothing operation.

Submit an order and it is still there after a reload, on another device, next week.

This matters for reading the phrase *"80% done, the other 20% is the backend."* In a distribution system that handles stock, debt and money, the data layer is not the final fifth of the work. It is the part that has to be correct, the part that takes longest, and the part that cannot be judged by looking at it.

A worked example. An order is two document numbers, four inserts and a stock movement. Done from a phone that is five separate requests with no way to undo them: a dropped signal halfway leaves a van decremented against an invoice that was never written. The current build posts it as one transaction that either completes or leaves nothing behind. That distinction is invisible on a screenshot and is the difference between a system that can be trusted with money and one that cannot.

THE PRACTICAL READING

The expensive, slow, invisible half is finished and tested. The visible half is where Coach Aril's design is strongest. **Those are complementary, and the sensible path uses both.**

04

What his design adds beyond the brief

Nineteen features appear in Coach Aril's screenshots that are not in the current build. The significant point is not the number — it is where they came from.

19	0	8	3
features added	of them specified in MASTER FINAL	now built, 2 part-built	that require database changes

ADDITION	IN MASTER FINAL?	CLASS	NOW
Product variants (flavours)	No	Schema	Blocked — needs a decision
Multi-branch operation (Selangor, Johor, Sabah)	No	Schema	Blocked — needs a decision
Free goods and combo products (FOC)	No	Schema	Blocked — needs a decision
Pending Acc Approval on payments	No — statuses listed are Paid, Partial, Pending, Overdue	Workflow	Built
Price change as an approval request	Permission is mentioned; an approval workflow is not	Workflow	Built
Request Credit Note	No — returns are specified, credit notes are not	Workflow	Built
Over Payment permitted	No	Rule change	Held — see question 9
Enable TIN QR (LHDN e-Invoice)	No — only “Tax / SST jika diperlukan”	Compliance	Part TIN stored and printed; QR needs LHDN

ADDITION	IN MASTER FINAL?	CLASS	NOW
Nearest Reseller map	Coordinates are stored; no map is specified	Screen	Part ranked by distance, Waze and Maps links; no map tile
GPS route recording	**Contradicts it** — tracking is explicitly excluded	Screen	Not built — contradicts the brief
Kerja Harian per-customer log	**Contradicts it** — visit tracking is explicitly excluded	Screen	Not built — contradicts the brief
Stock request as one document with many lines	No	Structure	Not built
Stock request running number	No — six sequences are listed, this is not among them	Field	Not built
Blacklist Reseller, as distinct from removal	No	Field	Built
Set VIP	No	Field	Built
Reseller Removed as a tracked metric	No	Field	Built
Per-outlet Service Month	No	Field	Built
Gaji as a payment method	Method is mentioned generically	Field	Built
Salesman photographs	No	Field	Not built

None of this is unreasonable to want. Several of the additions are plainly good ideas, and two of them – e-Invoice and product variants – would have to be built eventually regardless. **Eight have since been built and two more are part-built**, which is the most useful thing in this table: it converts an argument about scope into a list with dates against it.

But it should be stated plainly, because it governs timeline and budget: taken together, these nineteen items describe a **multi-branch distribution platform with layered internal approvals**, operating across at least three states. That is a materially larger system than the single-company field-sales tool MASTER FINAL describes, and it is a different class of build.

WORTH BEING DIRECT ABOUT

The question is not whether these features are worth having. It is whether they are inside the agreed scope or beyond it — and on the evidence of the requirement document, they are beyond it. **That makes them a second phase to be specified and costed, not a list of things missing from the first.**

05

What the additions cost

Grouped by effort rather than listed flat, because the nineteen are not remotely equal.

EFFORT	ITEMS	WHY
Hours each	Gaji payment method · payment comment · salesman photographs · Set VIP · Reseller Removed metric · per-outlet Service Month · stock request number · Blacklist state	A column, a flag or a label. Eight of the nineteen. **Five are now built; the estimate held.**
Days each	Pending Acc Approval · price-change approval · Request Credit Note · Over Payment handling · Nearest Reseller map · GPS route recording · Kerja Harian log · stock request restructure	A screen, or a workflow with two parties. Eight more. **Three are now built** — the three approval workflows, with the approver's side and the answer coming back, which took four days for all three together.
Weeks each	**Product variants · Multi-branch · Free goods**	Each one changes the database and touches every transaction built on it.

Why the last three are different

Product variants. *Observed* — the Stock Request form carries an **Edit Flavour** dropdown under every product. Dwangi is an air freshener; it comes in scents. If every product has variants, that dimension has to flow through van stock, order lines, consignment balances and every invoice line. The current product table is flat because the brief described flat products.

Multi-branch. *Observed* — salesman codes read `SEL001`, `JB005`, `SBH011`, and one entry reads literally *"JB003 SOLIHIN JOHOR BRANCH."* MASTER FINAL never mentions branches at all. This governs who may see whose data, which is enforced in the database, and it is far cheaper to design in than to retrofit.

Free goods. *Observed* — the Stock Request lists **Combo 3**, **Combo 1 FOC** and **Others**. The current build would refuse a zero-price line, because a floor-price guard was built deliberately to stop salesmen discounting away the margin. Allowing free goods means reworking that rule everywhere it applies.

All three are entirely buildable. All three cost a fraction as much decided now as decided after real outlets and real stock are loaded.

This is the only group that has not moved since 8 October, and it is not for want of time. Each needs a decision that is the client's to make, not ours: whether every product has variants, whether branches see each other's data, and whether a free line is allowed to break the floor-price rule. Everything else on the list could be started without asking anybody.

06

The missing approver

Four of the additions are approval workflows: a payment waits for **Pending Acc Approval**, a price change is submitted as **Mohon**, a stock request is **Approved**, and an invoice has to be issued as **Keluar Invois Muktamad**.

Every one of those needs a second person — someone in the office who sees the request and decides. **No such screen appeared anywhere in the forty screenshots.** His design is the salesman's half of four conversations that each require two parties.

The current build already had that half in the web portal. Since 8 October it also has it **on the phone**: signing in as the office swaps the tab bar — no van, so no stock and no GPS — and the home screen becomes the queue of what is waiting. Payments, price changes, credit notes and stock requests, each with Lulus and Tolak, and a rejection always asks why.

Two things were added that his screenshots do not show on either side, because four one-way workflows are not four workflows:

- **The answer goes back to the salesman.** He raises a Mohon or a credit note and sees the decision on his own phone, with the office's reason attached. Without it he telephones the office to find out, which is the thing the app was supposed to stop.
- **The office keeps a record of what it decided.** A queue that only shows what is waiting cannot answer “did we already deal with that?”, or “why was that price approved in March?”.

> If his design does have an admin side that simply was not shared, we should see it — it changes the estimate. If it does not, that office-side application is unbudgeted scope on his side, and **it is built and running on ours**, on the phone as well as in the browser.

07

Where both versions already agree

MASTER FINAL contradicts itself about Delivery Orders. Section B lists a DO in the Bil to Bil flow, while its own comparison table marks Bil to Bil as *not* sending stock ahead. If no stock goes ahead of the sale, there is nothing for a delivery order to deliver.

The current build resolved this by making **consignment the only source of a DO**, and structured the database so the alternative cannot happen by accident. Coach Aril's app resolved it the same way: his delivery order screen is titled **"Consignment Order"** and carries no total, because nothing is billed at the drop.

> Two independent readings reached the same answer against an ambiguous document. The hardest judgement in the data model is one both sides already share — which is a good indication the foundation is sound.

08

Contradictions and unknowns

Inside the requirement document

Cash is described twice, differently. Section C says `Order → Bill → Payment Terus → Receipt`. The Full Transaction Flow section says `ORDER → DO → SO → INVOICE → PAYMENT TERUS → RECEIPT`. These are different systems, and a ruling is needed.

Visit tracking is excluded, then built. MASTER FINAL states emphatically that Jadual Harian is not attendance, not visit tracking, and needs no pending or completed state. The current build followed that instruction and deliberately built less. His design contradicts it in three places: a **Kerja Harian Report**, GPS **Today / Past / Reset Route**, and a per-shop daily log. If the instruction has changed, that is a scope addition rather than an omission.

In the demo data

Several figures in his screenshots do not reconcile, which is expected of hardcoded sample data but prevented some rules being read with confidence:

- An order detail shows Total Paid `RM 0.00`, Total Pending `RM 0.00` and Total `RM 348.00`. The three do not add up.
- In Sales History, some rows marked **Paid** show `RM 0.00` and others `RM 40.00`. Unclear whether the figure is outstanding or paid.

- The Kesimpulan screen, by contrast, is internally consistent throughout, which is why its figures were the ones relied on here.

Labels nobody outside his team can read

LABEL	WHERE IT APPEARS	STATUS
TPP	“Kesimpulan Tpp & Rtn”	Unknown
RTN	Same	Probably Return
Pt. / Hc. / Tst	Stock Request quantity columns	Unknown
SE / SMS / NTN / SM	Reseller code prefixes	Unknown

> These cannot be built, because nobody outside his team knows what they mean. They also cannot be trained — a new salesman cannot be taught a column that has no name. **Recommendation: spell terms out in full in the interface, and keep a short written glossary for any that must stay short.**

09

Questions for Coach Aril

Every open question from the analysis, grouped by topic. Most take a minute to answer and would take weeks to discover the wrong way. Items marked Scope change the size of the job.

FOUR OF THESE HAVE BEEN ANSWERED PROVISIONALLY, NOT FINALLY

Where a decision could not wait, one was made and built so there is something concrete to accept or overrule rather than an empty space. All four remain open questions for Coach Aril.

- **Q4, the admin side.** Built — payments, price changes, credit notes and stock requests all decided from an office login, on the phone and in the browser. If his design has one too, we should still see it.
- **Set VIP.** Built as a label and a sort order only. What VIP should *give* a shop — a discount, delivery priority, a larger credit limit — was not invented. That part is still his to answer.
- **Enable TIN QR.** The buyer's TIN is stored and printed on the invoice. **No QR is generated.** The LHDN validation code exists only after LHDN validates the e-Invoice; one drawn by us would look like a government attestation without being one, which is not something to put on a customer's invoice. The deadline question stands.
- **Over Payment.** Deliberately not built. Taking more than is owed is still refused, pending question 9.

0 of **46** answered

Scope and sequencing 5

- [ ] 1 **Do all products have flavours or variants?** Which ones, and how many each? This is the largest single item in the report. SCOPE
- [ ] 2 **How many branches, and in which states?** Selangor, Johor and Sabah appear in the salesman codes. Nothing in the requirement mentions branches. SCOPE
- [ ] 3 How should **FOC** items be handled — a zero-price line on the invoice, or tracked outside it entirely? SCOPE
- [ ] 4 **Is there a management or admin side to the app?** Four approval workflows appear in the design with no screen for the approver. If there is one, we should see it; if not, who approves payments and price changes, issues stock and issues final invoices? SCOPE
- [ ] 5 Which additions are **needed at launch**, and which can follow? Several are a column; three are a rebuild of part of the database. SCOPE

Terminology 5

- [ ] 6 What does **TPP** stand for, and what does that column count?

- [ ] 7 What does **RTN** stand for — Return, or something else?
- [ ] 8 In the Stock Request table, what are the **Pt.**, **Hc.** and **Tst** columns?
- [ ] 9 What do the reseller code prefixes mean — **SE**, **SMS**, **NTN**, **SM**?
- [ ] 10 Are reseller codes **auto-generated**, or entered from the chain's own site codes? MASTER FINAL says the system must generate them, but the codes look like they come from Shell, Petron and Caltex.

Payment 6

- [ ] 11 What does **Pending Acc Approval** mean operationally — who approves, how long does it take, and what happens on rejection? KEY
- [ ] 12 Is **Total Pending** the amount awaiting that approval? *Our reading; it would explain the orange status.*
- [ ] 13 In the Sales History list, is the RM figure the **outstanding balance** or the **amount paid**?
- [ ] 14 Should **Over Payment** be allowed? The current build refuses it deliberately, as a safeguard. If allowed, does the excess carry forward as credit, or is it refunded? KEY
- [ ] 15 What is the **Gaji** payment method — salary deduction, and for whom?
- [ ] 16 Is the payment **comment** free text, and should it print on the receipt?

Pricing 3

- [ ] 17 Price change is a **Mohon** (request) — who approves it, and how quickly? A salesman standing at a counter cannot wait long.
- [ ] 18 Should there still be a **floor price** below which a salesman cannot go?
- [ ] 19 Does the audit trail MASTER FINAL asks for still apply — original price, requested price, final price, who changed it, when?

Products 4

- [ ] 20 What are **Combo 3** and **Combo 1 FOC** – products with their own SKU, or groups of other products?
- [ ] 21 What is the **Others** line in the Stock Request?
- [ ] 22 Can we have the **full product list** – SKUs, variants, Harga Kedai and Harga Jualan? KEY
- [ ] 23 The Stock Request asks for name, address, telephone, SO/DO number and order reference. Is stock ever delivered somewhere other than to the salesman?

Documents 5

- [ ] 24 **Keluar Invois Muktamad** – what happens between the Sales Order and the final invoice? Who issues it, and when?
- [ ] 25 **Request Credit Note** – when is a credit note used instead of a return? These are different documents with different accounting treatment.
- [ ] 26 Should the Order have its own running number (`ORD000001`)? MASTER FINAL lists one; neither version has one.
- [ ] 27 Should stock requests carry a running number like `RS014199`? Straightforward to add.
- [ ] 28 Running number format: MASTER FINAL specifies `SO000001`, the app shows `SO378767`. We assume the latter is demo data – please confirm.

Customer lifecycle 3

- [ ] 29 What is the difference between **Keluarkan Dari Apps** and **Blacklist Reseller**? We read the first as housekeeping and the second as a credit decision.
- [ ] 30 Why does the remove / reactivate button appear on **only some rows** in the reseller list?
- [ ] 31 What does **Set VIP** change – pricing, priority, visibility?

Schedule and tracking 3

- [ ] 32 MASTER FINAL says Jadual Harian is explicitly **not** visit tracking. The design tracks visits in three places. **Which instruction stands?** KEY
- [ ] 33 What does **Kerja Harian** record – what was done at the shop, or whether the salesman attended?
- [ ] 34 **Can we see the Jadual Harian screens?** They were never shared, and it is module 03. KEY

GPS 3

- [ ] 35 On the Nearest Reseller map, what do the **blue, green and red pins** mean?
- [ ] 36 **Answered – nothing needed here.** This previously asked whether GPS should be captured from the phone at registration. It already is: an outlet registered through the app stores a device fix taken standing at the shop. Only the seeded demo outlets carry coordinates approximated from their district, to about 600m, and the profile now says which of the two a pin is.
- [ ] 37 What does **Reset Route** do?

e-Invoice 2

- [ ] 38 **Enable TIN QR** is LHDN e-Invoice. What is the compliance deadline? This is the only item anywhere in this report that is a legal requirement rather than a preference. LEGAL
- [ ] 39 Is it enabled **per reseller**, outlet by outlet, as the screen suggests?

Consignment 2

- [ ] 40 **Where is the consignment balance entered?** Entering baki stock at the next visit is the heart of the consignment model, and no screen for it was shared. KEY
- [ ] 41 Service Month shows **1** – is the interval always monthly, or does it vary by outlet?

Confirmations and outstanding data 5

- [ ] 42 **Is Refer & Earn still wanted?** It is module 16, fully built and tested, and appears nowhere in the app design.

- [ ] 43 Is the **four-language switch** wanted? Bahasa Malaysia, English, Chinese and Iban are built. His design is Malay only.

- [ ] 44 Is the **public-facing panel** wanted?

- [ ] 45 Company **SSM number, registered address and phone** — needed for document headers. Invoices currently print a placeholder.

- [ ] 46 The **real outlet list** and **salesman list with email addresses**, so accounts can be opened and testing can begin on real data.

10

Recommendation

Build forward from the current system, and treat the additions as a specified, costed second phase.

- **The agreed brief is delivered.** All sixteen modules, running against a live database, with the business rules enforced where they cannot be bypassed. That is a finished first phase, and it should be signed off as one.
- **The hard half is the half that exists.** Transaction integrity, access control, collision-free document numbering and consignment reconciliation are the parts that take longest and cannot be judged by eye. Rebuilding them from a prototype would mean paying for them twice.
- **The form factor is no longer a question at all.** On 8 October this said a phone shell existed and that re-skinning would be cheap. Seven days later there are twenty-six screens built to his screenshots, running on the live database, with the office side on the phone beside the salesman's. That is the measure of what adopting his design costs, and it has already been paid.
- **His design should drive the interface, and it now does.** It is detailed, it is the client's own, and following it removed the largest source of rework. Where it improves on ours — the per-outlet consignment view, the customer profile layout — it was simply followed. Where it is silent, the requirement document was followed instead: **Jadual Harian** was never supplied, so it was built to the brief's explicit exclusions rather than invented.

- **The three schema items must be settled first.** Variants, branches and free goods are weeks of work each if decided late and days if decided now.

The alternative — restarting from the prototype — means rebuilding a tested data layer that already does the job. A week ago it could at least be said that the nineteen additions were unbuilt in both versions. **Eight of them are now built in one of them.**

11

Summary for the meeting

1. **All sixteen modules of the agreed requirement are built and running against a live database.** The brief has been delivered.

2. **His design now drives the screens.** Twenty-six of them, built to his screenshots in seven days, running on real rows — the salesman's whole day and the office's side of it. The interface question is settled.

3. Coach Aril's version remains a designed interface with hardcoded figures and no data layer. It shows what the system should look like; it cannot yet record a sale.

4. **Nineteen features in his design were never in the requirement document**, and two of them contradict it directly. They are worth having, but they are a second phase, not a list of omissions.

5. **Eight of those nineteen are now built and two are part-built**, including all three approval workflows with the approver's side. Of what remains, two are features the requirement document explicitly excludes.

6. **Three — product flavours, multiple branches and free goods — change the database and are the only things genuinely blocking the next phase.** They are the one group that has not moved, because each needs a decision that is the client's to make rather than ours.

7. His design contains four approval workflows and no screen for the approver. That office side is built and running on ours — on the phone as well as the browser — together with two things his design does not show at all: the salesman seeing what happened to his own requests, and the office keeping a record of what it decided.

8. **A document can be cancelled and everything it did reversed** — stock back on the van, payments undone, the shelf given up, the debt corrected. Neither the requirement nor his design mentions it. It is the first thing a real operation needs on the day somebody keys twenty instead of two.

9. Both versions independently departed from the requirement in the same place, on delivery orders, and both were right. The foundation is sound.

10. **Enable TIN QR is LHDN e-Invoice — the only legal deadline anywhere in this.** The buyer's TIN is now stored and printed on the invoice; the validation QR is LHDN's to issue, not ours to draw. We still need the date.

11. Several labels — TPP, RTN, Pt., Hc., Tst — cannot be read by anyone outside his team, and cannot be built until they are defined.

Based on approximately forty screenshots of Coach Aril's app and the MASTER FINAL requirement document. Claims about the current build were verified against the live Supabase project — the original report on 8 October 2026, this revision on 15 October 2026.
